HUMAN NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR COMPOSITIONS AND METHODS EMPLOYING SAME

RELATED APPLICATIONS

For U.S. national purposes, this application is a continuation-in-part of U.S. application Serial No. 08/484,722, by Elliott et al., entitled "HUMAN NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR
5 COMPOSITIONS AND METHODS EMPLOYING SAME", filed June 7, 1995. The subject matter of U.S. application Serial No. 08/484,722, is herein incorporated in its entirety by reference thereto.

This application is also related to U.S. Patent No. 5,369,028 and U.S. application Serial Nos. 08/028,031, 08/149,503, 08/496,855,
10 07/938,154, 08/467,574, 08/466,589, 08/487,596. The subject matter of each of these applications and U.S. Patent is herein incorporated by reference thereto.

FIELD OF INVENTION

This invention relates to nucleic acid molecules encoding human
15 neuronal nicotinic acetylcholine receptor protein subunits, as well as the encoded proteins. In particular, human neuronal nicotinic acetylcholine receptor α -subunit-encoding DNA and RNA, α -subunit proteins, β -subunit-encoding DNA and RNA, β -subunit proteins, and combinations thereof are provided.

20 BACKGROUND

Ligand-gated ion channels provide a means for communication between cells of the central nervous system. These channels convert a signal (e.g., a chemical referred to as a neurotransmitter) that is released by one cell into an electrical signal that propagates along a target cell
25 membrane. A variety of neurotransmitters and neurotransmitter receptors exist in the central and peripheral nervous systems. Five families of ligand-gated receptors, including the nicotinic acetylcholine receptors

-2-

(nAChRs) of neuromuscular and neuronal origins, have been identified (Stroud et al. 1990 Biochemistry 29:11009-11023). There is, however, little understanding of the manner in which the variety of receptors generates different responses to neurotransmitters or to other modulating
5 ligands in different regions of the nervous system.

The nicotinic acetylcholine receptors (nAChRs) are multisubunit proteins of neuromuscular and neuronal origins. These receptors form ligand-gated ion channels that mediate synaptic transmission between nerve and muscle and between neurons upon interaction with the
10 neurotransmitter acetylcholine (ACh). Since various neuronal nicotinic acetylcholine receptor (nAChR) subunits exist, a variety of nAChR compositions (i.e., combinations of subunits) exist. The different nAChR compositions exhibit different specificities for various ligands and are thereby pharmacologically distinguishable. Thus, the nicotinic
15 acetylcholine receptors expressed at the vertebrate neuromuscular junction, in vertebrate sympathetic ganglia and in the vertebrate central nervous system have been distinguished on the basis of the effects of various ligands that bind to different nAChR compositions. For example, the elapid α -neurotoxins that block activation of nicotinic acetylcholine
20 receptors at the neuromuscular junction do not block activation of some neuronal nicotinic acetylcholine receptors that are expressed on several different neuron-derived cell lines.

Muscle nAChR is a glycoprotein composed of five subunits with the stoichiometry $(\alpha)_2\beta(\gamma \text{ or } \epsilon)\delta$. Each of the subunits has a mass of
25 about 50-60 kilodaltons (kd) and is encoded by a different gene. The $(\alpha)_2\beta(\gamma \text{ or } \epsilon)\delta$ complex forms functional receptors containing two ligand binding sites and a ligand-gated transmembrane channel. Upon interaction with a cholinergic agonist, muscle nicotinic nAChRs conduct sodium ions. The influx of sodium ions rapidly short-circuits the normal

-3-

ionic gradient maintained across the plasma membrane, thereby depolarizing the membrane. By reducing the potential difference across the membrane, a chemical signal is transduced into an electrical signal at the neuromuscular junction that induces muscle contraction.

- 5 Functional muscle nicotinic acetylcholine receptors have been formed with $\alpha\beta\delta\gamma$ subunits, $\alpha\beta\gamma$ subunits, $\alpha\beta\delta$ subunits, $\alpha\delta\gamma$ subunits, but not only with one subunit (see, e.g., Kurosaki et al. (1987) FEBS Lett. 214 253-258; Comacho et al. (1993) J. Neuroscience 13:605-613). In contrast, functional neuronal nAChRs can be formed from α subunits
- 10 alone or combinations of α and β subunits. The larger α subunit is generally believed to be a ACh-binding subunit and the lower molecular weight β subunit is generally believed to be the structural subunit, although it has not been definitely demonstrated that the β subunit does not have the ability to bind ACh or participate in the formation of the ACh
- 15 binding site. Each of the subunits which participate in the formation of a functional ion channel are, to the extent they contribute to the structure of the resulting channel, "structural" subunits, regardless of their ability (or inability) to bind ACh. Neuronal nAChRs, which are also ligand-gated ion channels, are expressed in ganglia of the autonomic nervous system
- 20 and in the central nervous system (where they mediate signal transmission), and in pre- and extra-synaptic locations (where they modulate neurotransmission and may have additional functions; Wonnacott et al. (1990) In: progress in Brain Research, A. Nordberg et al., Eds., Elsevier, Amsterdam) 157-163.
- 25 DNA encoding nAChRs has been isolated from several sources. Based on the information available from such work, it has been evident for some time that nAChRs expressed in muscle, in autonomic ganglia, and in the central nervous system are functionally diverse. This functional diversity could be due, at least in part, to the large number of

-4-

different nAChR subunits which exist. There is an incomplete understanding, however, of how (and which) nAChR subunits combine to generate unique nAChR subtypes, particularly in neuronal cells. Indeed, there is evidence that only certain nAChR subtypes may be involved in
5 disease such as Alzheimer's disease. Moreover, it is not clear whether nAChRs from analogous tissues or cell types are similar across species.

Accordingly, there is a need for the isolation and characterization of DNAs encoding each human neuronal nAChR subunit, recombinant cells containing such subunits and receptors prepared therefrom. In order
10 to study the function of human neuronal nAChRs and to obtain disease-specific pharmacologically active agents, there is also a need to obtain isolated (preferably purified) human neuronal nAChRs, and isolated (preferably purified) human neuronal nAChR subunits. In addition, there is also a need to develop assays to identify such pharmacologically active
15 agents.

The availability of such nucleic acids, cells, receptor subunits and receptor compositions will eliminate the uncertainty of speculating as to human neuronal nAChR structure and function based on predictions drawn from non-human nAChR data, or human or non-human muscle or
20 ganglia nAChR data.

Therefore, it is an object herein to isolate and characterize DNA encoding subunits of human neuronal nicotinic acetylcholine receptors. It is also an object herein to provide methods for recombinant production of human neuronal nicotinic acetylcholine receptor subunits. It is also an
25 object herein to provide purified receptor subunits and to provide methods for screening compounds to identify compounds that modulate the activity of human neuronal nAChRs.

These and other objects will become apparent to those of skill in the art upon further study of the specification and claims.

-5-

SUMMARY OF THE INVENTION

Isolated nucleic acid molecules encoding human alpha (α) and beta (β) subunits of neuronal nAChRs are provided. In particular, isolated DNA and RNA molecules encoding human α_6 and β_3 subunits of neuronal nAChRs are provided. Messenger RNA and polypeptides encoded by the DNA are also provided.

Recombinant human neuronal nicotinic nAChR subunits, including α_6 and β_3 subunits, as well as methods for the production thereof are also provided. In addition, recombinant human neuronal nicotinic acetylcholine receptors containing at least one human neuronal nicotinic nAChR subunit are also provided, as well as methods for the production thereof. Also provided are recombinant neuronal nicotinic nAChRs that contain a mixture of one or more nAChR subunits encoded by a host cell, and one or more nAChR subunits encoded by heterologous DNA or RNA (*i.e.*, DNA or RNA as described herein that has been introduced into the host cell), as well as methods for the production thereof.

Plasmids containing DNA encoding the above-described subunits are also provided. Recombinant cells containing the above-described DNA, mRNA or plasmids are also provided herein. Such cells are useful, for example, for replicating DNA, for producing human nAChR subunits and recombinant receptors, and for producing cells that express receptors containing one or more human subunits.

The DNA, RNA, vectors, receptor subunits, receptor subunit combinations and cells provided herein permit production of selected neuronal nicotinic nAChR receptor subtypes and specific combinations thereof, as well as antibodies to the receptor subunits. This provides a means to prepare synthetic or recombinant receptors and receptor subunits that are substantially free of contamination from many other receptor proteins whose presence can interfere with analysis of a single

-6-

nAChR subtype. The availability of desired receptor subtypes makes it possible to observe the effect of a drug substance on a particular receptor subtype and to thereby perform initial *in vitro* screening of the drug substance in a test system that is specific for humans and specific for a human neuronal nicotinic nAChR subtype.

Also provided herein, are single-stranded probes containing portions of the DNA molecules described herein and antibodies that specifically bind to proteins encoded by the DNA. Also provided herein is an isolated nucleic acid molecule containing nucleotides 98-211 of SEQ ID NO:15.

Proteins encoded by the DNA are also provided. The proteins may be prepared by expressing the DNA in a suitable prokaryotic or eukaryotic host cell and isolating the resulting protein.

Methods for identifying functional neuronal nicotinic acetylcholine receptor subunits and combinations thereof are also provided.

Assays for identifying compounds that modulate the activity of human nicotinic acetylcholine receptors are also provided. The ability to screen drug substances *in vitro* to determine the effect of the drug on specific receptor compositions should permit the development and screening of receptor subtype-specific or disease-specific drugs. Also, testing of single receptor subunits or specific receptor subtype combinations with a variety of potential agonists or antagonists provides additional information with respect to the function and activity of the individual subunits and should lead to the identification and design of compounds that are capable of very specific interaction with one or more of the receptor subunits or receptor subtypes. The resulting drugs should exhibit fewer unwanted side effects than drugs identified by screening with cells that express a variety of subtypes.

-7-

Further in relation to drug development and therapeutic treatment of various disease states, the availability of DNA and RNA encoding human neuronal nAChR subunits provides a means for identification of any alterations in such genes (e.g., mutations) that may correlate with the occurrence of certain disease states. In addition, the creation of animal models of such disease states becomes possible, by specifically introducing such mutations into synthetic DNA sequences which can then be introduced into laboratory animals or *in vitro* assay systems to determine the effects thereof.

10 BRIEF DESCRIPTION OF FIGURES

Figure 1 presents a restriction map of a cytomegalovirus (CMV) promoter-based vector pcDNA3-KEalpha6.3 that contains an α_6 -encoding fragment as an *EcoRI* insert.

Figure 2 presents a restriction map of a CMV promoter-based vector pcDNA3-KBbeta3.2 that contains a β_3 -encoding fragment as an *EcoRI* insert.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

Definitions

Unless defined otherwise, all technical and scientific terms used herein have the same meaning as is commonly understood by one of skill in the art to which this invention belongs. All patents and publications referred to herein are, unless noted otherwise, incorporated by reference in their entirety.

As used herein, isolated (or substantially purified or pure) as a modifier of nucleic acid molecule, DNA, RNA, polypeptides or proteins means that the DNA, RNA, polypeptides or proteins so-designated have been separated from their *in vivo* cellular environments through the hand of man. Thus, for example, as used herein, isolated (or substantially pure) DNA refers to DNA fragments purified according to standard

-8-

techniques employed by those skilled in the art (see, e.g., Maniatis et al. (1982) Molecular Cloning: A Laboratory Manual, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY).

Similarly, as used herein, "recombinant" as a modifier of DNA,
5 RNA, polypeptides or proteins means that the DNA, RNA, polypeptides or proteins so designated have been prepared by the efforts of human beings, e.g., by cloning, recombinant expression, or such method. Thus, as used herein, recombinant proteins, for example, refers to proteins produced by a recombinant host expressing DNAs which have been
10 added to that host through the efforts of human beings.

As used herein, vector (or plasmid) refers to discrete elements that are used to introduce heterologous DNA into cells for either expression or replication thereof. Selection and use of such vehicles are well within the level of skill of the art. An expression vector includes vectors capable of
15 expressing DNA that is operatively linked with regulatory sequences, such as promoter regions, that are capable of effecting expression of such DNA fragments. Thus, an expression vector refers to a recombinant DNA or RNA construct, such as plasmid, a phage, recombinant virus or other vector that, upon introduction to a host cell, allows expression of DNA
20 cloned into the appropriate site on the vector. Appropriate expression vectors are well known to those of skill in the art and include those that are replicable in eukaryotic cells and/or prokaryotic cells and those that remain episomal or those which integrate into the host cell genome. Presently preferred plasmids for expression of the nAChR subunits in
25 eukaryotic host cells, particularly mammalian cells, include, but are not limited to, cytomegalovirus (CMV), Simian virus 40 (SV40) and mouse mammary tumor virus (MMTV) promoter-containing vectors such as pCMV, pcDNA1, pcDNA3, pZeoSV, pCEP4, pMAMneo and pMAMhyg.

-9-

As used herein, a promoter region refers to a segment of DNA that controls transcription of DNA to which it is operatively linked. The promoter region includes specific sequences that are sufficient for RNA polymerase recognition, binding and transcription initiation. This portion of the promoter region is referred to as the promoter. In addition, the promoter region includes sequences that modulate this recognition, binding and transcription initiation activity of RNA polymerase. These sequences may be *cis* acting or may be responsive to *trans* acting factors. Promoters, depending upon the nature of the regulation, may be constitutive or regulated. Exemplary promoters contemplated for use herein include the SV40 early promoter, the cytomegalovirus (CMV) promoter, the mouse mammary tumor virus (MMTV) steroid-inducible promoter, and Moloney murine leukemia virus (MMLV) promoter, and other suitable promoters.

As used herein, the term "operatively linked" refers to the functional relationship of DNA with regulatory and effector sequences of nucleotides, such as promoters, enhancers, transcriptional and translational start and stop sites, and other signal sequences. For example, operative linkage of DNA to a promoter refers to the physical and functional relationship between the DNA and the promoter such that the transcript of such DNA is initiated from the promoter by an RNA polymerase that specifically recognizes, binds to and transcribes the DNA. In order to optimize expression and/or *in vitro* transcription, it may be necessary to remove or alter 5' untranslated portions of the clones to remove extra, potential alternative translation initiation (i.e., start) codons or other sequences that interfere with or reduce expression, either at the level of transcription or translation. Alternatively, consensus ribosome binding sites (see, for example, Kozak (1991) J. Biol. Chem. 266:19867-19870) can be inserted immediately 5' of the start codon to enhance

-10-

expression. The desirability of (or need for) such modification may be empirically determined.

As used herein, expression refers to the process by which polynucleic acids are transcribed into mRNA and translated into peptides, polypeptides, or proteins. If the polynucleic acid is derived from genomic DNA, expression may, if an appropriate eukaryotic host cell or organism is selected, include splicing of the mRNA.

Particularly preferred vectors for transfection of mammalian cells are the SV40 promoter-based expression vectors, such as pZeoSV (Invitrogen, San Diego, CA), CMV promoter-based vectors such as pcDNA1, pcDNA3, pCEP4 (Invitrogen, San Diego, CA), and MMTV promoter-based vectors such as pMAMneo (Clontech, Inc.).

As used herein, a human alpha (α) subunit gene is a gene that encodes an alpha subunit of a human neuronal nicotinic acetylcholine receptor. Alpha subunits of human nAChRs typically exhibit a conservation of adjacent cysteine residues in the presumed extracellular domain of the subunit that are the homologs of cysteines 192 and 193 of the *Torpedo* alpha subunit (see Noda et al. (1982) Nature 299:793-797).

As used herein, an alpha subunit subtype refers to a human neuronal nAChR subunit that is encoded by DNA that hybridizes under high stringency conditions to at least one of the neuronal nAChR alpha subunit-encoding DNA clones disclosed herein. An alpha subunit generally binds to ACh under physiological conditions and at physiological concentrations and, in the optional presence of a beta subunit (i.e., some alpha subunits are functional alone, while others require the presence of a beta subunit), generally forms a functional nAChR as assessed by methods described herein or known to those of skill in this art.

Also contemplated are alpha subunits encoded by DNA molecules that encode alpha subunits as defined above, but that by virtue of

-11-

degeneracy of the genetic code do not necessarily hybridize to the disclosed DNA under specified hybridization conditions. Such subunits also form a functional receptor, as assessed by the methods described herein or known to those of skill in the art, generally with one or more

5 beta subunit subtypes. Typically, unless an alpha subunit is encoded by RNA that arises from alternative splicing (i.e., a splice variant), alpha-encoding DNA and the alpha subunit encoded thereby share substantial sequence homology with at least one of the alpha subunit DNAs (and proteins encoded thereby) described herein. It is understood that DNA or

10 RNA encoding a splice variant may overall share less than 90% homology with the DNA or RNA provided herein, but include regions of nearly 100% homology to a DNA fragment described herein, and encode an open reading frame that includes start and stop codons and encodes a functional alpha subunit.

15 As used herein, a human beta (β) subunit gene is a gene that encodes a beta subunit of a human neuronal nicotinic acetylcholine receptor. Assignment of the name "beta" to a putative neuronal nAChR subunit has been based on the lack of adjacent cysteine residues (which residues are characteristic of alpha subunits). The beta subunit is

20 frequently referred to as the structural nAChR subunit (although it is possible that beta subunits also have ACh binding properties). Combination of the appropriate beta subunit(s) with appropriate alpha subunit(s) leads to the formation of a functional receptor.

As used herein, a beta subunit subtype refers to a neuronal nAChR

25 subunit that is encoded by DNA that hybridizes under high stringency conditions to at least one of the neuronal nAChR-encoding DNAs disclosed herein. A beta subunit may form a functional nAChR, as assessed by methods described herein or known to those of skill in this art, with appropriate alpha subunit subtype(s).

-12-

Also contemplated are beta subunits encoded by DNA that encodes beta subunits as defined above, but that by virtue of degeneracy of the genetic code do not necessarily hybridize to the disclosed DNA under the specified hybridization conditions. Such subunits may also form

5 functional receptors, as assessed by the methods described herein or known to those of skill in the art, in combination with appropriate alpha subunit subtype(s). Typically, unless a beta subunit is encoded by RNA that arises as a splice variant, beta-encoding DNA and the beta subunit encoded thereby share substantial sequence homology with the beta-

10 encoding DNA and beta subunit protein described herein. It is understood that DNA or RNA encoding a splice variant may share less than 90% overall homology with the DNA or RNA provided herein, but such DNA will include regions of nearly 100% homology to the DNA described herein.

15 As used herein, a nAChR subtype refers to a nicotinic acetylcholine receptor containing a particular combination of α and/or β subunit subtypes, e.g., a receptor containing human nAChR α_6 and β_3 subunits.

As used herein, a splice variant refers to variant nAChR subunit-encoding nucleic acid(s) produced by differential processing of primary

20 transcript(s) of genomic DNA, resulting in the production of more than one type of mRNA. cDNA derived from differentially processed genomic DNA will encode nAChR subunits that have regions of complete amino acid identity and regions having different amino acid sequences. Thus, the same genomic sequence can lead to the production of multiple,

25 related mRNAs and proteins. The resulting mRNA and proteins are referred to as "splice variants".

As used herein, heterologous or foreign DNA and RNA are used interchangeably and refer to DNA or RNA that does not occur naturally as part of the genome in which it is present or which is found in a location

-13-

or locations in the genome that differ from that in which it occurs in nature. It is typically DNA or RNA that is not endogenous to the cell and has been artificially introduced into the cell. Examples of heterologous DNA include, but are not limited to, DNA that encodes a human nAChR subunit and DNA that encodes RNA or proteins that mediate or alter expression of endogenous DNA by affecting transcription, translation, or other regulatable biochemical processes. The cell that expresses the heterologous DNA, such as DNA encoding a human nAChR subunit, may contain DNA encoding the same or different nicotinic acetylcholine receptor subunits. The heterologous DNA need not be expressed and may be introduced in a manner such that it is integrated into the host cell genome or is maintained episomally.

Stringency of hybridization is used herein to refer to conditions under which polynucleic acid hybrids are stable. As known to those of skill in the art, the stability of hybrids is reflected in the melting temperature (T_m) of the hybrids. T_m can be approximated by the formula: $81.5^{\circ}\text{C} - 16.6 (\log_{10}[\text{Na}^+]) + 0.41 (\%G + C) - 600/l$, where l is the length of the hybrids in nucleotides. T_m decreases approximately $1-1.5^{\circ}\text{C}$ with every 1% decrease in sequence homology. In general, the stability of a hybrid is a function of sodium ion concentration and temperature. Typically, the hybridization reaction is performed under conditions of lower stringency, followed by washes of varying, but higher, stringency. Reference to hybridization stringency relates to such washing conditions.

As used herein:

(1) HIGH STRINGENCY conditions, with respect to fragment hybridization, refer to conditions that permit hybridization of only those nucleic acid sequences that form stable hybrids in 0.018M NaCl at 65°C (i.e., if a hybrid is not stable in 0.018M NaCl at 65°C , it will not be stable

-14-

under high stringency conditions, as contemplated herein). High stringency conditions can be provided, for example, by hybridization in 50% formamide, 5X Denhardt's solution, 5X SSPE, 0.2% SDS, 200 μ g/ml denatured sonicated herring sperm DNA, at 42°C, followed by
5 washing in 0.1X SSPE, and 0.1% SDS at 65°C;

(2) MODERATE STRINGENCY conditions, with respect to fragment hybridization, refer to conditions equivalent to hybridization in 50% formamide, 5X Denhardt's solution, 5X SSPE, 0.2% SDS, 200 μ g/ml denatured sonicated herring sperm DNA, at 42°C, followed by washing in
10 0.2X SSPE, 0.2% SDS, at 60°C;

(3) LOW STRINGENCY conditions, with respect to fragment hybridization, refer to conditions equivalent to hybridization in 10% formamide, 5X Denhardt's solution, 6X SSPE, 0.2% SDS, 200 μ g/ml denatured sonicated herring sperm DNA, followed by washing in 1X
15 SSPE, 0.2% SDS, at 50°C; and

(4) HIGH STRINGENCY conditions, with respect to oligonucleotide (i.e., synthetic DNA \leq about 30 nucleotides in length) hybridization, refer to conditions equivalent to hybridization in 10% formamide, 5X Denhardt's solution, 6X SSPE, 0.2% SDS, 200 μ g/ml denatured
20 sonicated herring sperm DNA, at 42°C, followed by washing in 1X SSPE, and 0.2% SDS at 50°C.

It is understood that these conditions may be duplicated using a variety of buffers and temperatures and that they are not necessarily precise.

25 Denhardt's solution and SSPE (see, e.g., Sambrook et al. (1989) Molecular Cloning: A Laboratory Manual, 2nd Ed., Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY) are well known to those of skill in the art as are other suitable hybridization buffers. For example, SSPE is pH 7.4 phosphate-buffered 0.18M NaCl. SSPE can be prepared,

-15-

for example, as a 20X stock solution by dissolving 175.3 g of NaCl, 27.6 g of NaH_2PO_4 and 7.4 g EDTA in 800 ml of water, adjusting the pH to 7.4, and then adding water to 1 liter. Denhardt's solution (see, Denhardt (1966) Biochem. Biophys. Res. Commun. 23:641) can be prepared, for
5 example, as a 50X stock solution by mixing 5 g Ficoll (Type 400, Pharmacia LKB Biotechnology, INC., Piscataway NJ), 5 g of polyvinylpyrrolidone, 5 g bovine serum albumin (Fraction V; Sigma, St. Louis MO) water to 500 ml and filtering to remove particulate matter.

As used herein, the phrase "substantial sequence homology" refers
10 to two sequences of nucleotides that share at least about 90% identity, and amino acid sequences which typically share greater than 95% amino acid identity. It is recognized, however, that proteins (and DNA or mRNA encoding such proteins) containing less than the above-described level of homology arising as splice variants or that are modified by conservative
15 amino acid substitutions (or substitution of degenerate codons) are contemplated herein.

The phrase "substantially the same" is used herein in reference to the nucleotide sequence of DNA, the ribonucleotide sequence of RNA, or the amino acid sequence or protein, that have slight and non-
20 consequential sequence variations from the actual sequences disclosed herein. Species that are substantially the same are considered to be functionally equivalent to the disclosed sequences. Thus, as used herein functionally equivalent nucleic acid molecules or proteins are those that are sufficiently similar to function in substantially the same manner to
25 achieve substantially the same results.

As used herein, "slight and non-consequential sequence variations" mean that sequences that are substantially the same as the DNA, RNA, or proteins disclosed and claimed herein are functionally equivalent to the human-derived sequences disclosed and claimed herein. Functionally

-16-

equivalent sequences will function in substantially the same manner to produce substantially the same compositions as the human-derived nucleic acid and amino acid compositions disclosed and claimed herein. In particular, functionally equivalent DNA molecules encode human-

5 derived proteins that are the same as those disclosed herein or that have conservative amino acid variations, such as substitution of a non-polar residue for another non-polar residue or a charged residue for a similarly charged residue (see, e.g., Table 1). These changes include those recognized by those of skill in the art as those that do not substantially

10 alter the tertiary structure of the protein.

Suitable conservative substitutions of amino acids are known to those of skill in this art and may be made generally without altering the biological activity of the resulting molecule. Those of skill in this art recognize that, in general, single amino acid substitutions in non-essential

15 regions of a polypeptide do not substantially alter biological activity (see, e.g., Watson et al. *Molecular Biology of the Gene*, 4th Edition, 1987, The Benjamin/Cummings Pub. co., p.224). Such substitutions are preferably made in accordance with those set forth in TABLE 1 as follows:

20

TABLE 1

	Original residue	Conservative substitution
	Ala (A)	Gly; Ser
	Arg (R)	Lys
	Asn (N)	Gln; His
25	Cys (C)	Ser; neutral amino acids
	Gln (Q)	Asn
	Glu (E)	Asp
	Gly (G)	Ala; Pro
	His (H)	Asn; Gln
30	Ile (I)	Leu; Val
	Leu (L)	Ile; Val
	Lys (K)	Arg; Gln; Glu
	Met (M)	Leu; Tyr; Ile
	Phe (F)	Met; Leu; Tyr
35	Ser (S)	Thr
	Thr (T)	Ser
	Tyr (W)	Tyr

Conservative substitution
Trp; Phe
Ile; Leu

Other substitutions are also permissible and may be determined
5 empirically or in accord with known conservative substitutions. Any such modification of the polypeptide may be effected by any means known to those of skill in this art.

As used herein, activity of a human neuronal nAChR refers to any activity characteristic of an nAChR. Such activity can typically be
10 measured by one or more *in vitro* methods, and frequently corresponds to an *in vivo* activity of a human neuronal nAChR. Such activity may be measured by any method known to those of skill in the art, such as, for example, measuring the amount of current which flows through the recombinant channel in response to a stimulus.

15 Methods to determine the presence and/or activity of human neuronal nAChRs include, but are not limited to, assays that measure nicotine binding, ^{86}Rb ion-flux, Ca^{2+} influx, the electrophysiological response of cells, the electrophysiological response of oocytes injected with RNA. In particular, methods are provided herein for the
20 measurement or detection of an nAChR-mediated response upon contact of cells containing the DNA or mRNA with a test compound.

As used herein, a recombinant or heterologous human neuronal nAChR refers to a receptor that contains one or more subunits encoded by heterologous DNA that has been introduced into and expressed in cells
25 capable of expressing receptor protein. A recombinant human neuronal nAChR may also include subunits that are produced by DNA endogenous to the host cell. In certain embodiments, recombinant or heterologous human neuronal nAChR may contain only subunits that are encoded by heterologous DNA.

-18-

As used herein, a functional neuronal nAChR is a receptor that exhibits an activity of neuronal nicotinic nAChRs as assessed by any *in vitro* or *in vivo* assay disclosed herein or known to those of skill in the art. Possession of any such activity that may be assessed by any

5 methods known to those of skill in the art and provided herein is sufficient to designate a receptor as functional. Methods for detecting nAChR protein and/or activity include, but are not limited to, for example, assays that measure nicotine binding, ^{86}Rb ion-flux, Ca^{2+} influx and the electrophysiological response of cells containing heterologous DNA or

10 mRNA encoding one or more receptor subunit subtypes. Since all combinations of alpha and beta subunits may not form functional receptors, numerous combinations of alpha and beta subunits may be tested in order to fully characterize a particular subunit and cells which produce same. Thus, as used herein, "functional" with respect to a

15 recombinant or heterologous human neuronal nAChR means that the receptor channel is able to provide for and regulate entry of human neuronal nAChR-permeable ions, such as, for example, Na^+ , K^+ , Ca^{2+} or Ba^{2+} , in response to a stimulus and/or bind ligands with affinity for the receptor. Preferably such human neuronal nAChR activity is

20 distinguishable, such as by electrophysiological, pharmacological and other means known to those of skill in the art, from any endogenous nAChR activity that may be produced by the host cell.

As used herein, one type of a "control" cell or "control" culture is a cell or culture that is treated substantially the same as the cell or culture

25 exposed to the test compound except that the control culture is not exposed to the test compound. Another type of a "control" cell or "control" culture may be a cell or a culture of cells which are identical to the transfected cells except the cells employed for the control culture do not express functional nicotinic acetylcholine receptors. In this situation,

-19-

the response of test cell to the test compound is compared to the response (or lack of response) of the nicotinic acetylcholine receptor-negative cell to the test compound, when cells or cultures of each type of cell are exposed to substantially the same reaction

5 conditions in the presence of the compound being assayed.

As used herein, a compound or signal that "modulates the activity of a neuronal nAChR" refers to a compound or signal that alters the activity of nAChR so that activity of the nAChR is different in the presence of the compound or signal than in the absence of the compound

10 or signal. In particular, such compounds or signals include agonists and antagonists. The term agonist refers to a substance or signal, such as ACh, that activates receptor function; and the term antagonist refers to a substance that interferes with receptor function. Typically, the effect of an antagonist is observed as a blocking of activation by an agonist.

15 Antagonists include competitive and non-competitive antagonists. a competitive antagonist (or competitive blocker) interacts with or near the site specific for the agonist (e.g., ligand or neurotransmitter) for the same or closely situated site. A non-competitive antagonist or blocker inactivates the functioning of the receptor by interacting with a site other

20 than the site that interacts with the agonist.

A. Isolated DNA clones

DNA molecules encoding human alpha and beta subunits of neuronal nAChRs are provided. Specifically, isolated DNAs encoding α_6 and β_3 subunits of human neuronal nAChRs are described herein.

25 Recombinant messenger RNA (mRNA) and recombinant polypeptides encoded by the above-described DNA are also provided.

For purposes herein, " α_6 subunit-encoding nucleic acid " refers to DNA or RNA encoding a neuronal nicotinic acetylcholine receptor subunit of the same name. Such nucleic acid molecules can be characterized in a

-20-

number of ways, for example the nucleotides of the DNA (or ribonucleotides of the RNA) may encode the amino acid sequence set forth in SEQ ID NO:10 or SEQ ID NO:20.

- Presently preferred α_6 -encoding nucleic acid includes DNA or RNA
- 5 that hybridizes to the coding sequence set forth in SEQ ID NO:9 (preferably to substantially the entire coding sequence thereof, i.e., nucleotides 143-1624) or SEQ ID NO:19 (preferably to substantially the entire coding sequence thereof, i.e., nucleotides 143-1579) under high stringency conditions.
- 10 Especially preferred α_6 -encoding nucleic acid molecules are those that encode a protein having substantially the same amino acid sequence (i.e., with only conservative amino acid substitutions) as that set forth in SEQ ID NO:10 or SEQ ID NO:20. Most preferred molecules include a
- 15 sequence of nucleotides (or ribonucleotides with U substituted for T) having substantially the same sequence of nucleotides as set forth in SEQ ID NO: 9 (i.e., particularly nucleotides 143-1624 thereof) or SEQ ID NO:19 (i.e., particularly nucleotides 143-1579 thereof).

- Typically, unless an α_6 subunit arises as a splice variant, α_6 -encoding DNA will share substantial sequence homology (i.e. greater than
- 20 about 90%), with a α_6 -encoding nucleic acid molecules described herein. DNA or RNA encoding a splice variant may share less than 90% overall sequence homology with the DNA or RNA provided herein, but such a splice variant would include regions of nearly 100% homology to one or more of the nucleic acid molecules provided herein.

- 25 Also provided herein are " β_3 subunit-encoding nucleic acids", which include DNA or RNA molecules that encode a neuronal nicotinic acetylcholin receptor subunit of the same name. Such nucleic acid molecules can be characterized in a number of ways, for example, the

-21-

nucleotides of the DNA (or ribonucleotides of the RNA) may encode the amino acid sequence set forth in SEQ ID NO:16.

- Presently preferred β_3 -encoding nucleic acid includes DNA or RNA that hybridizes under high stringency conditions to the coding sequence set forth in SEQ ID NO:15 (preferably to substantially the entire coding sequence thereof, i.e., nucleotides 98-1471). More preferred are those nucleic acids that encode a protein that includes the sequence of amino acids (or substantially the sequence of amino acids with only conservative amino acid substitutions) set forth in SEQ ID NO:16.
- 5 Especially preferred β_3 -encoding nucleic acid molecules provided herein have substantially the same nucleotide sequence as set forth in SEQ ID NO:15 (i.e., particularly nucleotides 98-1471 thereof).

- Typically, unless a β_3 subunit arises as a splice variant, β_3 -encoding nucleic acid will share substantial sequence homology (greater than about 15 90%) with the β_3 -encoding nucleic acid molecules described herein. DNA or RNA encoding a splice variant may share less than 90% overall sequence homology with the DNA or RNA provided herein, but such nucleic would include regions of nearly 100% homology to one or more of the above-described nucleic acid molecules.

20 B. Probes

- DNA encoding human neuronal nicotinic nAChR alpha and beta subunits may be isolated by screening suitable human cDNA or human genomic libraries under suitable hybridization conditions with the DNA disclosed herein (including nucleotides derived from SEQ ID NOs:9 or 15).
- 25 Suitable libraries can be prepared from tissues such as neuronal tissue samples, basal ganglia, thalamus, and hypothalamus tissues. The library is preferably screened with a portion of DNA including the entire subunit-encoding sequence thereof, or the library may be screened with a suitable

-22-

probe. Typically probes are labeled with an identifiable tag, such as a radiolabel, enzyme or other such tag known to those of skill in the art.

Probes for use in methods of isolating α_6 - and β_3 -encoding nucleic acids are also provided. Thus, for example, with reference to human α_6 subunits, a probe is a single-stranded DNA or RNA molecule that has a sequence of nucleotides that includes at least 27 contiguous bases that are the same as (or the complement of) any 27 bases set forth in SEQ ID NO:9 or SEQ ID NO:19.

With reference to human β_3 subunits, a probe is single-stranded DNA or RNA that has a sequence of nucleotides that includes at least 28 contiguous bases that are the same as (or the complement of) any 28 bases derived from the first 105 nucleotides of signal sequence/coding sequence set forth in SEQ ID NO:15.

Among the preferred regions from which to construct probes include, but are not limited to, 5' and/or 3' coding sequences, regions containing sequences predicted to encode transmembrane domains, regions containing sequences predicted to encode a cytoplasmic loop, signal sequences, and acetylcholine (ACh) and α -bungarotoxin (α -bgtx) binding sites. Amino acids that correspond to residues 190-198 of the *Torpedo* nAChR α subunit (see, e.g., Karlin (1993) Curr. Opin. Neurobiol. 3:299-309) are typically involved in ACh and α -bgtx binding. The approximate amino acid residues which include such regions for other probes are set forth in the following table, Table 2:

	Subunit	Signal Sequence	TMD1*	TMD2	TMD3	TMD4	Cytoplasmic loop
25	α_6 *	1-30	240-265	272-294	301-326	458-483	327-457
	β_3	1-20	231-258	265-287	293-318	421-446	319-420

* TMD = transmembrane domain

* With reference to the amino acid sequence shown in SEQ ID NO:10.

-23-

Alternatively, portions of the DNA can be used as primers to amplify selected fragments in a particular library.

5 C. Isolation of clones encoding α_6 and β_3 subunits of human neuronal nicotinic acetylcholine receptors

The probes are used to screen a suitable library. Suitable libraries for obtaining DNA encoding each subunit include, but are not limited to: substantia nigra, thalamus or hypothalamus to isolate human α_6 -encoding DNA and substantia nigra or thalamus to isolate human β_3 -encoding DNA.

10 After screening the library, positive clones are identified by detecting a hybridization signal; the identified clones are characterized by restriction enzyme mapping and/or DNA sequence analysis, and then examined, by comparison with the sequences set forth herein, to ascertain whether they include DNA encoding a complete alpha or beta

15 subunit. If the selected clones are incomplete, they may be used to rescreen the same or a different library to obtain overlapping clones. If desired, the library can be rescreened with positive clones until overlapping clones that encode an entire alpha or beta subunit are obtained. If the library is a cDNA library, then the overlapping clones will

20 include an open reading frame. If the library is genomic, then the overlapping clones may include exons and introns. Complete clones may be identified by comparison with the DNA and encoded proteins provided herein.

Complementary DNA clones encoding various subtypes of human

25 neuronal nAChR alpha and beta subunits have been isolated. Each subtype of the subunit appears to be encoded by a different gene. The DNA clones provided herein may be used to isolate genomic clones encoding each subtype and to isolate any splice variants by screening libraries prepared from different neural tissues. Nucleic acid amplification

30 techniques, which are well known in the art, can be used to locate splice

-24-

- variants of human neuronal nAChR subunits. This is accomplished by employing oligonucleotides based on DNA sequences surrounding divergent sequence(s) as primers for amplifying human RNA or genomic DNA. Size and sequence determinations of the amplification products
- 5 can reveal the existence of splice variants. Furthermore, isolation of human genomic DNA sequences by hybridization can yield DNA containing multiple exons, separated by introns, that correspond to different splice variants of transcripts encoding human neuronal nAChR subunits.
- 10 It has been found that not all subunit subtypes are expressed in all neural tissues or in all portions of the brain. Thus, in order to isolate cDNA encoding particular subunit subtypes or splice variants of such subtypes, it is preferable to screen libraries prepared from different neuronal or neural tissues.
- 15 **D. Cells and vectors containing α_6 - and β_3 -encoding nucleic acids**
- The above-described nucleic acid molecules encoding human nAChR subunits can be incorporated into vectors for further manipulation. Incorporation of cloned DNA into a suitable expression vector,
- 20 constructs encoding one or more distinct genes or with linear DNA, and selection of transfected cells are well known in the art (see, e.g., Sambrook *et al.* (1989) Molecular Cloning: A Laboratory Manual, 2nd Ed., Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY).
- Heterologous DNA may be introduced into host cells by any method
- 25 known to those of skill in the art, such as transfection with an expression construct encoding the heterologous DNA by CaPO_4 precipitation (see, e.g., Wigler *et al.* (1979) Proc. Natl. Acad. Sci. U.S.A. 76:1373-1376). Recombinant cells can then be cultured under conditions whereby the subunit(s) encoded by the DNA is (are) expressed. Preferred cells

-25-

include, but are not limited to, mammalian cells (e.g., HEK 293, CHO and Ltk cells), yeast cells (e.g., methylotrophic yeast cells, such as *Pichia pastoris*) and bacterial cells (e.g., *Escherichia coli*).

The nucleic acids encoding α_6 or β_3 subunits can be incorporated
5 into vectors individually or in combination with nucleic acids encoding other nicotinic acetylcholine receptor subunits for further manipulation. Full-length DNA clones encoding human neuronal nAChR subunits have been inserted into vector pcDNA3, a pUC19-based mammalian cell expression vector containing the CMV promoter/enhancer, a polylinker
10 downstream of the CMV promoter/enhancer, followed by the bovine growth hormone (BGH) polyadenylation signal. Placement of nAChR subunit-encoding DNA between the CMV promoter and BGH polyadenylation signal provides for constitutive expression of the DNA in a mammalian host cell transfected with the construct. For inducible
15 expression of human nAChR subunit-encoding DNA in a mammalian cell, the DNA can be inserted into a plasmid such as pMAMneo. This plasmid contains the mouse mammary tumor virus (MMTV) promoter for steroid-inducible expression of operatively associated foreign DNA. If the host cell does not express endogenous glucocorticoid receptors required for
20 uptake of glucocorticoids (i.e., inducers of the MMTV promoter) into the cell, it is necessary to additionally transfect the cell with DNA encoding the glucocorticoid receptor (ATCC accession no. 67200).

In accordance with another embodiment, there are provided cells containing the above-described polynucleic acids (i.e., DNA or mRNA).
25 Host cells such as bacterial, yeast and mammalian cells can be used for replicating DNA and producing nAChR subunit(s). Methods for constructing expression vectors, preparing *in vitro* transcripts, transfecting DNA into mammalian cells, injecting oocytes, and performing electrophysiological and other analyses for assessing receptor expression

-26-

and function as described herein are also described in PCT Application Nos. PCT/US91/02311, PCT/US94/02447, PCT/US91/05625, and PCT/US92/11090, in U.S. Patent No. 5,369,028, and in co-pending U.S. Application Serial Nos. 07/563,751 and 07/812,254. The subject matter
5 of these applications is hereby incorporated by reference herein in its entirety.

While the DNA provided herein may be expressed in any eukaryotic cell, including yeast cells (such as, for example, *Pichia*, particularly *Pichia pastoris* (see U.S. Patent Nos. 4,882,279, 4,837,148, 4,929,555 and
10 4,855,231), *Saccharomyces cerevisiae*, *Candida tropicalis*, *Hansenula polymorpha*, and other yeast cells), mammalian expression systems, including commercially available systems and other such systems known to those of skill in the art, for expression of DNA encoding the human neuronal nicotinic nAChR subunits provided herein are presently
15 preferred. *Xenopus* oocytes are preferred for expression of RNA transcripts of the DNA.

Cloned full-length DNA encoding any of the subunits of human neuronal nicotinic nAChR may be introduced into a plasmid vector for expression in a eukaryotic cell. Such DNA may be genomic DNA or
20 cDNA. Host cells may be transfected with one or a combination of plasmids, each of which encodes at least one human neuronal nAChR subunit. Heterologous DNA may be maintained in the cell as an episomal element or may be integrated into chromosomal DNA of the cell.

Eukaryotic cells in which DNA or RNA may be introduced include
25 any cells that are transfectable by such DNA or RNA or into which such DNA or RNA may be injected. Preferred cells are those that can be transiently or stably transfected and also express the DNA and RNA. Presently most preferred cells are those that can form recombinant or heterologous human neuronal nicotinic nAChRs containing one or more

-27-

subunits encoded by the heterologous DNA. Such cells may be identified empirically or selected from among those known to be readily transfected or injected.

Exemplary cells for introducing DNA include, but are not limited to, cells of mammalian origin (e.g., COS cells, mouse L cells, Chinese hamster ovary (CHO) cells, human embryonic kidney (HEK) cells, GH3 cells and other such cells known to those of skill in the art, amphibian cells (e.g., *Xenopus laevis* oöcytes) and yeast cells (e.g., *Saccharomyces cerevisiae*, *Pichia pastoris*). Exemplary cells for expressing injected RNA transcripts include *Xenopus laevis* oöcytes. Cells that are preferred for transfection of DNA are known to those of skill in the art or may be empirically identified, and include HEK 293 (which are available from ATCC under accession #CRL 1573); Ltk⁻ cells (which are available from ATCC under accession #CCL1.3); COS-7 cells (which are available from ATCC under accession #CRL 1651); and GH3 cells (which are available from ATCC under accession #CCL82.1). Presently preferred cells include GH3 cells and HEK 293 cells, particularly HEK 293 cells that have been adapted for growth in suspension and that can be frozen in liquid nitrogen and then thawed and regrown. HEK 293 cells are described, for example, in U.S. Patent No. 5,024,939 to Gorman (see, also, Stillman et al. (1985) Mol. Cell. Biol. 5:2051-2060).

DNA can be stably incorporated into cells or may be transiently introduced using methods known in the art. Stably transfected mammalian cells may be prepared by transfecting cells either with one or more expression constructs carrying DNA encoding nAChR subunits and a separate expression vector carrying a selectable marker gene (e.g., but not limited to, the gene for neomycin resistance, zeocin resistance, or hygromycin resistance) or with one or more expression constructs which carry the DNA encoding nAChR subunit and the selectable marker, and

-28-

growing the transfected cells under conditions selective for cells expressing the marker gene(s). To produce such cells, the cells should be transfected with a sufficient concentration of subunit-encoding nucleic acids to form human neuronal nAChRs that contain the human subunits
5 encoded by heterologous DNA. The precise amounts and ratios of DNA encoding the subunits may be empirically determined and optimized for a particular combination of subunits, cells and assay conditions.

Recombinant cells that express neuronal nAChR containing subunits encoded only by the heterologous DNA or RNA are especially preferred.

10 **E. Recombinant nAChRs and nAChR Subunit Proteins**

Provided herein are substantially pure human nAChR subunit proteins, particularly human α_6 and β_3 subunit proteins. Also provided herein are recombinant nAChR containing at least one of the human nAChR subunit proteins. Thus, a further embodiment provided herein
15 contains methods of producing recombinant human nAChR subunits and receptors containing the subunits.

In preferred embodiments, DNA encoding human nAChR subunit(s), particularly human nAChR α_6 and/or β_3 subunits, is ligated into a vector, and the resulting construct is introduced into suitable host cells to
20 produce transformed cell lines that express a specific human neuronal nAChR receptor subtype, or specific combinations of subtypes. The resulting cell lines can then be produced in quantity for reproducible quantitative analysis of the effects of drugs on receptor function. In other embodiments, mRNA may be produced by *in vitro* transcription of
25 DNA encoding each subunit. This mRNA, either from a single subunit clone or from a combination of clones, can then be injected into *Xenopus* oocytes where the mRNA directs the synthesis of the human receptor subunits, which then form functional receptors. Alternatively, the subunit-encoding DNA can be directly injected into oocytes for expression

-29-

of functional receptors. The transfected mammalian cells or injected oocytes may then be used in the methods of drug screening provided herein.

The resulting recombinant cells may be cultured or subcultured (or
5 passaged, in the case of mammalian cells) from such a culture or a subculture thereof. Methods for transfection, injection and culturing recombinant cells are known to the skilled artisan. Similarly, the human neuronal nicotinic nAChR subunits may be purified using protein purification methods known to those of skill in the art. For example,
10 antibodies or other ligands that specifically bind to one or more of the subunits may be used for affinity purification of the subunit or human neuronal nAChRs containing the subunits.

In accordance with one embodiment, methods for producing cells that express human neuronal nAChR subunits and functional receptors
15 are also provided. In one such method, host cells are transfected with DNA encoding at least one alpha subunit of a neuronal nAChR and at least one beta subunit of neuronal nAChR. Using methods such as northern blot or slot blot analysis, transfected cells that contain alpha and/or beta subunit encoding DNA or RNA can be selected. Transfected
20 cells are also analyzed to identify those that express nAChR protein. Analysis can be carried out, for example, by measuring the ability of cells to bind acetylcholine, nicotine, or a nAChR agonist, compared to the nicotine binding ability of untransfected host cells or other suitable control cells, or by electrophysiologically monitoring the currents through
25 the cell membrane in response to a nAChR agonist.

In particularly preferred aspects, eukaryotic cells that contain heterologous DNA, express such DNA and form recombinant functional neuronal nAChR(s) are provided. In more preferred aspects, recombinant neuronal nAChR activity is readily detectable because it is a type that is

-30-

absent from the untransfected host cell or is of a magnitude not exhibited in the untransfected cell. Such cells that contain recombinant receptors could be prepared, for example, by causing cells transformed with DNA encoding the human neuronal nicotinic nAChR α_6 and β_3 subunits to

5 express the corresponding proteins in the presence or absence of one or more alpha and/or beta nAChR subunits. The resulting synthetic or recombinant receptor would contain the α_6 and β_3 nAChR subunits. Such a receptor would be useful for a variety of applications, e.g., as part of an assay system free of the interferences frequently present in prior art

10 assay systems employing non-human receptors or human tissue preparations. Furthermore, testing of single receptor subunits with a variety of potential agonists or antagonists would provide additional information with respect to the function and activity of the individual subunits. Such information may lead to the identification of compounds

15 which are capable of very specific interaction with one or more of the receptor subunits. Such specificity may prove of great value in medical application.

Thus, DNA encoding one or more human neuronal nAChR subunits may be introduced into suitable host cells (e.g., eukaryotic or prokaryotic

20 cells) for expression of individual subunits and functional nAChRs. Preferably combinations of alpha and beta subunits may be introduced into cells: such combinations include combinations of any one or more of α_2 , α_3 , α_4 , α_5 , α_6 and α_7 with β_2 , β_3 and/or β_4 . Sequence information for each of these subunits is presented in the Sequence Listing provided

25 herewith. Sequence information for α_5 is also presented in Proc. Natl. Acad. Sci. USA (1992) 89:1572-1576; sequence information for α_2 , α_3 , α_4 , α_7 , β_2 and β_4 is also presented in PCT publication WO 94/20617, incorporated by reference herein. Presently preferred combinations of subunits include α_6 and/or β_3 with any one or more of α_2 , α_3 , α_4 , α_5 , β_2 or

-31-

β_4 . It is recognized that some of the subunits may have ion transport function in the absence of additional subunits, while others require a combination of two or more subunits in order to display ion transport function. For example, the α_7 subunit is functional in the absence of any added beta subunit. Furthermore, some of the subunits may not form functional nAChRs alone or in combination, but instead may modulate the properties of other nAChR subunit combinations.

In certain embodiments, eukaryotic cells with heterologous human neuronal nAChRs are produced by introducing into the cells a first composition, which contains at least one RNA transcript that is translated in the cell into a subunit of a human neuronal nAChR. In preferred embodiments, the subunits that are translated include an alpha subunit of a human neuronal nAChR. More preferably, the composition that is introduced contains a RNA transcript which encodes an alpha subunit and also contains a RNA transcript which encodes a beta subunit of a human neuronal nAChR. RNA transcripts can be obtained from cells transfected with DNAs encoding human neuronal nAChR subunits or by *in vitro* transcription of subunit-encoding DNAs. Methods for *in vitro* transcription of cloned DNA and injection of the resulting mRNA into eukaryotic cells are well known in the art. Amphibian oocytes are particularly preferred for expression of *in vitro* transcripts of the human neuronal nAChR DNA clones. See e.g., Dascal (1989) CRC Crit. Rev. Biochem. 22:317-387, for a review of the use of *Xenopus oocytes* to study ion channels.

Thus, a stepwise introduction into cells of DNA or RNA encoding one or more alpha subtypes, and one or more beta subtypes is possible. The resulting cells may be tested by the methods provided herein or known to those of skill in the art to detect functional nAChR activity. Such testing will allow the identification of combinations of alpha and

-32-

beta subunit subtypes that produce functional nAChRs, as well as individual subunits that produce functional nAChRs.

Recombinant receptors on recombinant eukaryotic cell surfaces may contain one or more subunits encoded by the DNA or mRNA
5 encoding human neuronal nAChR subunits, or may contain a mixture of subunits encoded by the host cell and subunits encoded by heterologous DNA or mRNA. Recombinant receptors may be homogeneous or may be a mixture of subtypes. Mixtures of DNA or mRNA encoding receptors from various species, such as rats and humans, may also be introduced
10 into the cells. Thus, a cell may be prepared that expresses recombinant receptors containing only α_6 and β_3 subunits, or in combination with any other alpha and beta subunits provided herein. For example, either or both of the α_6 and β_3 subunits provided herein can be co-expressed with α_2 , α_3 , α_4 , α_5 , α_7 , β_2 and/or β_4 receptor subunits. As noted previously,
15 some of the neuronal nAChR subunits may be capable of forming functional receptors in the absence of other subunits, thus co-expression is not always required to produce functional receptors. Moreover, some nAChR subunits may require co-expression with two or more nAChR subunits to participate in functional receptors.

20 F. Assays

In accordance with one embodiment provided herein, recombinant human neuronal nAChR-expressing mammalian cells or oocytes can be contacted with a test compound, and the modulating effect(s) thereof can then be evaluated by comparing the nAChR-mediated response in the
25 presence and absence of test compound, or by comparing the nAChR-mediated response of test cells, or control cells to the presence of the compound.

As understood by those of skill in the art, assay methods for identifying compounds that modulate human neuronal nAChR activity

-33-

(e.g., agonists and antagonists) generally require comparison to a control. As noted above, one type of a "control" cell or "control" culture is a cell or culture that is treated substantially the same as the cell or culture exposed to the test compound, except the control culture is not exposed to test compound. For example, in methods that use voltage clamp electrophysiological procedures, the same cell can be tested in the presence and absence of test compound, by merely changing the external solution bathing the cell. Another type of "control" cell or "control" culture may be a cell or a culture of cells which are identical to the transfected cells, except the cells employed for the control culture do not express functional human neuronal nAChRs. In this situation, the response of test cell to test compound is compared to the response (or lack of response) of receptor-negative (control) cell to test compound, when cells or cultures of each type of cell are exposed to substantially the same reaction conditions in the presence of compound being assayed.

Functional recombinant human neuronal nAChRs include at least an alpha subunit, or at least an alpha subunit and a beta subunit of a human neuronal nAChR. Eukaryotic cells expressing these subunits have been prepared by injection of RNA transcripts and by transfection of DNA. Such cells have exhibited nAChR activity attributable to human neuronal nAChRs that contain one or more of the heterologous human neuronal nAChR subunits.

With respect to measurement of the activity of functional heterologous human neuronal nAChRs, endogenous nAChR activity and, if desired, activity of nAChRs that contain a mixture of endogenous host cell subunits and heterologous subunits, should, if possible, be inhibited to a significant extent by chemical, pharmacological and electrophysiological means.

-34-

G. Antibodies

Also provided herein are antibodies generated against the above-described nAChR subunits or portions thereof. Such antibodies may be employed for assessing receptor tissue localization, subtype composition, structure of functional domains, purification of receptors, as well as in diagnostic and therapeutic applications. Preferably for therapeutic applications, the antibodies employed will be monoclonal antibodies.

The above-described antibodies can be prepared employing standard techniques, as are well known to those of skill in the art, using the nAChR subunit proteins, or portions thereof, described herein as antigens for antibody production. Both anti-peptide and anti-fusion protein antibodies can be used [see, for example, Bahouth *et al.* (1991) Trends Pharmacol. Sci. 12:338-343; Current Protocols in Molecular Biology (Ausubel *et al.*, eds.), John Wiley and Sons, New York (1989)]. Factors to consider in selecting portions of the nAChR subunits for use as immunogen (as either a synthetic peptide or a recombinantly produced bacterial fusion protein) include antigenicity, accessibility (i.e., extracellular and cytoplasmic domains), uniqueness to the particular subtype, and other factors known to those of skill in this art.

The availability of subtype-specific antibodies makes possible the application of the technique of immunochemistry to monitor the distribution and expression density of various subtypes (e.g., in normal vs. diseased brain tissue). The antibodies produced using the human nAChR subunits as immunogens have, among other properties, the ability to specifically and preferentially bind to and/or cause the immunoprecipitation of human nAChR or a subunit thereof which may be present in a biological sample or a solution derived from such a sample. Such antibodies may also be used to selectively isolate cells that express human nAChR that contain the subunit for which the antibodies are

-35-

specific. Such antibodies could also be employed for diagnostic and therapeutic applications. In a further embodiment, there are provided methods for modulating the ion channel activity of nAChRs by contacting the receptors with an effective amount of the above-described antibodies.

- 5 The antibodies herein can be administered to a subject employing standard methods, such as, for example, by intraperitoneal, intramuscular, intravenous, or subcutaneous injection, implant or transdermal modes of administration. One of skill in the art can readily determine dose forms, treatment regimens, etc., depending on the mode
10 of administration employed.

The following examples are included for illustrative purposes only and are not intended to limit the scope of the invention.

EXAMPLE 1

Isolation of DNA Encoding Human nAChR α_6 Subunits

- 15 A human substantia nigra cDNA library (Clontech Laboratories, Inc.) was screened for hybridization to a fragment of the rat nAChR α_6 subunit cDNA. Isolated plaques were transferred to nitrocellulose filters and hybridization was performed in 5X Denhardt's, 5X SSPE, 50% formamide, 200 μ g/ml denatured salmon sperm DNA and 0.2% SDS, at
20 42°C. Washes were performed in 0.2X SSPE, 0.2% SDS, at 60°C.

- Five hybridizing clones were plaque-purified and characterized by restriction endonuclease mapping and DNA sequence analysis. The DNA sequence of the 5'- and 3'-ends of the cDNA inserts was determined using commercially available λ gt10 forward and reverse
25 oligonucleotide primers. Analysis of the DNA sequence of the five cDNA inserts revealed that three clones contained the translational initiation codon, a full-length α_6 open reading frame (nucleotides 143-1624 of SEQ ID NO:9), the translational stop codon and 142 additional nucleotides of 5'- and 116 nucleotides of 3'- flanking sequences. The amino acid

-36-

sequence deduced from the nucleotide sequence of the full-length clone has ~82% identity with the amino acid sequence deduced from the rat nAChR α_6 subunit DNA. Several regions of the deduced rat and human α_6 amino acid sequences are notably dissimilar:

- 5 amino acids 1-30 (the human signal sequence has only ~56% identity with respect to the rat sequence),
amino acids 31-50 (the human sequence has only ~70% identity with respect to the rat sequence),
amino acids 344-391 (the human sequence has only ~40%
10 identity with respect to the rat sequence),
amino acids 401-428 (the human sequence has only ~64% identity with respect to the rat sequence).

- Furthermore, the insert DNA of a single clone, KE α 6.5, was determined to be missing 45 nucleotides of α_6 coding sequence, resulting
15 in an in-frame deletion of 15 amino acid residues of the deduced amino acid sequence (residues 74 to 88 of SEQ ID NO:10). The nucleotide sequence of an α_6 subunit variant lacking this sequence is shown in SEQ ID NO:19 and the amino acid sequence deduced therefrom is shown in SEQ ID NO:20. Interestingly, the deduced amino acid sequence
20 immediately downstream of the site of the deletion shares only ~58% amino acid identity with the deduced rat α_6 amino acid sequence (amino acids 89-100 of SEQ ID NO:10).

EXAMPLE 2

Isolation of DNA Encoding A Human nAChR β_3 Subunit

- 25 A human substantia nigra cDNA library (Clontech Laboratories, Inc.) was screened for hybridization to synthetic oligonucleotides complementary to the human nicotinic nAChR β_3 subunit cDNA. Isolated plaques were transferred to nitrocellulose filters and hybridized under high stringency conditions with respect to oligonucleotides (washing

-37-

conditions 1X SSPE, 0.2% SDS at 50°C) with synthetic oligonucleotides complementary to sequences of the human β_3 nAChR subunit cDNA that include nucleotides 212-230 and 1442-1469 of SEQ ID NO:15.

Two hybridizing clones were plaque-purified and characterized by
5 restriction endonuclease mapping. The DNA sequence of the 5'- and 3'-
ends of the cDNA insert was determined using commercially available T7
and SP6 oligonucleotide primers. The complete sequence of clone
KB β 3.2 was determined. Clone KB β 3.2 contains a 1927 bp cDNA insert
that contains a 1,377-nucleotide open reading frame encoding a full-
10 length β_3 nAChR subunit (nucleotides 98-1471 SEQ ID NO:15) as well as
97 nucleotides of 5'- and 454 nucleotides of 3'-untranslated sequence.
The amino acid sequence deduced from the nucleotide sequence of the
full-length clone has ~81% identity with the amino acid sequence
deduced from the rat nicotinic nAChR β_3 subunit DNA. Several regions of
15 the deduced rat and human β_3 amino acid sequences are notably
dissimilar:

amino acids 1-28 (the human signal sequence has only ~25%
identity with respect to the rat sequence),

amino acids 347-393 (the human sequence has only ~55%
20 identity with respect to the rat sequence),

amino acids 440-464 (the human sequence has only ~68%
identity with respect to the rat sequence).

EXAMPLE 3

25 Preparation of Constructs for the Expression of Recombinant Human Neuronal nAChR Subunits

Isolated cDNAs encoding human neuronal nAChR subunits were
incorporated into vectors for use in expressing the subunits in mammalian
host cells and for use in generating *in vitro* transcripts from the DNAs to

-38-

be expressed in *Xenopus* oocytes. The following vectors were utilized in preparing the constructs.

A. Constructs for Expressing Human nAChR α_6 Subunits

- A 1,743 bp *EcoRI* fragment, encoding a full-length nAChR α_6 subunit, was isolated from KE α 6.3 by standard methods and ligated into the *EcoRI* polylinker site of the vector pcDNA3 to generate pcDNA3-KE α 6.3 (see Figure 1). Plasmid pcDNA3 (see Figure 1) is a pUC19-based vector that contains a CMV promoter/enhancer, a T7 bacteriophage RNA polymerase promoter positioned downstream of the CMV promoter/enhancer, a bovine growth hormone (BGH) polyadenylation signal downstream of the T7 promoter, and a polylinker between the T7 promoter and the BGH polyadenylation signal. This vector thus contains all of the regulatory elements required for expression in a mammalian host cell of heterologous DNA which has been incorporated into the vector at the polylinker. In addition, because the T7 promoter is located just upstream of the polylinker, this plasmid can be used for the synthesis of *in vitro* transcripts of heterologous DNA that has been subcloned into the vector at the polylinker. Furthermore, this plasmid contains a gene encoding neomycin resistance used as a selectable marker during transfection.

Figure 1 also shows a partial restriction map of pcDNA3-KE α 6.3.

- The expression of the full-length human nAChR α_6 subunit was optimized by the introduction of a consensus ribosome binding site [RBS; see, e.g., Kozak (1991) *J. Biol. Chem.* 266:19867-19870] prior to the translational start codon. The existing 5'-untranslated region was modified by PCR mutagenesis using the plasmid pcDNA3-KE α 6.3 as a DNA template and a complementary upstream oligonucleotide containing the appropriate nucleotide RBS substitutions as well as flanking 5' *HindIII* and *EcoRI* sites, and an oligonucleotide complementary to α_6 coding

-39-

sequences ~450 nucleotides downstream of the translational start codon. The resulting amplification product contained *Hind*III and *Eco*RI sites followed by the consensus RBS and nucleotides 1-459 of the human nAChR α_6 coding sequence (nucleotides 143-602 of SEQ ID NO:9). The amplified DNA was digested with *Hind*III and *Bam*HI; the 308-bp *Hind*III-*Bam*HI fragment was isolated and ligated with the 5.3 kb *Bam*HI-*Pvu*I fragment of pcDNA3-KE α 6.3 and the 1.4-kb *Pvu*I to *Hind*III fragment from pcDNA3 to generate the ~7.0 kb plasmid pcDNA3-KE α 6RBS.

B. Constructs for Expressing Human Neuronal nAChR β_3 Subunits

An ~2.0 kb *Eco*RI fragment, encoding a full-length nicotinic AChR β_3 subunit, was isolated from KB β 3.2 by standard methods and ligated into the *Eco*RI polylinker site of the vector pcDNA3 to generate pcDNA3-KB β 3.2 (see Figure 2). Figure 2 also shows a partial restriction map of pcDNA3.KB β 3.2.

The expression of the full-length human nicotinic nAChR β_3 subunit is optimized by the introduction of a consensus ribosome binding site (RBS) prior to the translational start codon. The existing 5'-untranslated region is modified by PCR mutagenesis using a method similar to that described above for the α_6 nAChR subunit to generate pcDNA3-KB β 3RBS.

EXAMPLE 4

Expression of Recombinant Human Neuronal nAChR in *Xenopus*

Xenopus oocytes are injected with *in vitro* transcripts prepared from constructs containing DNA encoding α_6 and β_3 subunits. Electrophysiological measurements of the oocyte transmembrane currents are made using the two-electrode voltage clamp technique (see, e.g., Stuhmer (1992) *Meth. Enzymol.* 207:310-339).

-40-

1. Preparation of *in vitro* transcripts

Recombinant capped transcripts of pcDNA3-KE α RBS and pcDNA3-KB β 3RBS are synthesized from linearized plasmids using the mMessage and mMachine *in vitro* transcription kit according to the capped transcript
5 protocol provided by the manufacturer (Catalog 1344 from AMBION, Inc., Austin, TX). The mass of the synthesized transcripts is determined by UV absorbance and the integrity of the transcripts is determined by electrophoresis through an agarose gel.

2. Electrophysiology

10 *Xenopus* oocytes are injected with either 12.5, 50 or 125 ng of one or more human nicotinic nAChR α and β subunit transcript per oocyte. The preparation and injection of oocytes is carried out as described by Dascal (1987) in *Crit. Rev. Biochem.* 22:317-387. Two-to-six days following mRNA injection, the oocytes are examined using the
15 two-electrode voltage clamp technique. The cells are bathed in Ringer's solution (115 mM NaCl, 2.5 mM KCl, 1.8 mM CaCl₂, 10 mM HEPES, pH 7.3) containing 1 μ M atropine with or without 100 μ M d-tubocurarine. Cells are voltage-clamped at -60 to -80 mV. Data are acquired with Axotape software at 2-5 Hz. The agonists acetylcholine (ACh), nicotine,
20 and cytisine are added at concentrations ranging from 0.1 μ M to 100 μ M.

EXAMPLE 5

Recombinant Expression of Human nAChR Subunits in Mammalian Cells

Human embryonic kidney (HEK) 293 cells are transiently and stably transfected with DNA encoding human neuronal nicotinic nAChR α_6 and
25 β_3 subunits. Transient transfectants are analyzed for expression of nicotinic nAChR using various assays, e.g., electrophysiological methods, Ca²⁺-sensitive fluorescent indicator-based assays.

-41-

1. Transient Transfection of HEK Cells

HEK cells are transiently co-transfected with DNA encoding one or more α subunit and/or one or more β subunits. Approximately 2×10^6 HEK cells are transiently transfected with 18 μg of the indicated
5 plasmid(s) according to standard CaPO_4 transfection procedures (Wigler et al. (1979) Proc. Natl. Acad. Sci. U.S.A. 76:1373-1376) or using lipofectamine according to the manufacturer's instructions (Bethesda Research Laboratory (BRL), Gaithersburg, MD). In addition, 2 μg of plasmid pCMV β gal (Clontech Laboratories, Palo Alto, CA), which contains
10 the *Escherichia coli* β -galactosidase gene fused to the CMV promoter, are co-transfected as a reporter gene for monitoring the efficiency of transfection. The transfectants are analyzed for β -galactosidase expression by measurement of β -galactosidase activity [Miller (1972) Experiments in Molecular Genetics, pp. 352-355, Cold Spring Harbor
15 Press]. Transfectants can also be analyzed for β -galactosidase expression by direct staining of the product of a reaction involving β -galactosidase and the X-gal substrate [Jones (1986) *EMBO* 5:3133-3142].

2. Stable Transfection of HEK Cells

HEK cells are transfected using the calcium phosphate transfection
20 procedure [*Current Protocols in Molecular Biology*, Vol. 1, Wiley Inter-Science, Supplement 14, Unit 9.1.1-9.1.9 (1990)]. HEK cells are transfected with 1 ml of DNA/calcium phosphate precipitate containing the DNA encoding the desired alpha and beta subunits and pSV2neo (as a selectable marker). After 14 days of growth in medium containing
25 1 $\mu\text{g}/\text{ml}$ G418, colonies form and are individually isolated by using cloning cylinders. The isolates are subjected to limiting dilution and screened to identify those that expressed the highest level of nAChR, as described below.

-42-

EXAMPLE 6**Characterization of Cell Lines Expressing Human Neuronal nAChRs**

Recombinant cell lines generated by transfection with DNA
5 encoding human neuronal nAChR subunits, such as those described in
EXAMPLE 5, can be further characterized using one or more of the
following methods.

**A. Northern or slot blot analysis for expression of α - and/or
 β -subunit encoding messages**

10 Total RNA is isolated from $\sim 1 \times 10^7$ cells and 10-15 μg of RNA
from each cell type is used for Northern or slot blot hybridization analysis.
The inserts from human neuronal nAChR-encoding plasmids can be nick-
translated and used as probe. In addition, a fragment of the
glyceraldehyde-3-phosphate dehydrogenase (GAPD) gene sequence (Tso
15 et al. (1985) Nucleic Acids Res. 13:2485) can be nick-translated and
used as a control probe on duplicate filters to confirm the presence or
absence of RNA on each blot and to provide a rough standard for use in
quantitating differences in α - or β - specific mRNA levels between cell
lines. Typical Northern and slot blot hybridization and wash conditions
20 are as follows:

hybridization in 5x SSPE, 5X Denhardt's solution, 0.2% SDS, 200 $\mu\text{g}/\text{ml}$
denatured, sonicated herring sperm DNA, 50% formamide, at 42°C
followed by washing in 0.1x SSPE, 0.1% SDS, at 65°C.

B. Binding assay

25 Cell lines generated by transfection with human neuronal nAChR α -
or α - and β -subunit-encoding DNA can be analyzed for their ability to bind
nicotine or other agonist, for example, as compared to control cell lines:
e.g., neuronally-derived cell lines PC12 (Boulter et al. (1986) Nature
319:368-374; ATCC #CRL1721) and IMR32 (Clementi, et al. (1986) Int.
30 J. Neurochem. 47:291-297; ATCC #CCL127), and muscle-derived cell

-43-

line BC3H1 (Patrick, *et al.* (1977) *J. Biol. Chem.* 252:2143-2153).

Negative control cells (*i.e.*, host cells from which the transfectants were prepared) are also included in the assay. The assay is conducted as follows:

- 5 Just prior to being assayed, transfected cells are removed from plates by scraping. Positive control cells used are PC12, BC3H1, and IMR32 (which had been starved for fresh media for seven days). Control cell lines are removed by rinsing in 37°C assay buffer (50mM Tris/HCl, 1 mM MgCl₂, 2 mM CaCl₂, 120 mM NaCl, 3 mM EDTA, 2 mg/ml BSA and 0.1% aprotinin at pH 7.4).
- 10 The cells are washed and resuspended to a concentration of $1 \times 10^6/250 \mu\text{l}$. To each plastic assay tube is added 250 μl of the cell solution, 15 nM ³H-nicotine, with or without 1 mM unlabeled nicotine, and assay buffer to make a final volume of 500 μl . The assays for the transfected cell lines are incubated for 30 min at room
- 15 temperature; the assays of the positive control cells are incubated for 2 min at 1°C. After the appropriate incubation time, 450 μl aliquots of assay volume are filtered through Whatman GF/C glass fiber filters which have been pretreated by incubation in 0.05% polyethylenimine for 24 hours at 4°C. The filters are then washed twice, with 4 ml each wash,
- 20 with ice cold assay buffer. After washing, the filters are dried, added to vials containing 5 ml scintillation fluid and radioactivity is measured.

C. ⁸⁶Rb ion-flux assay

- The ability of nicotine or nAChR agonists and antagonists to mediate the influx of ⁸⁶Rb into transfected and control cells has been
- 25 found to provide an indication of the presence of functional nAChRs on the cell surface. The ⁸⁶Rb ion-flux assay is conducted as follows:
 1. The night before the experiment, cells are plated at 2×10^6 per well (*i.e.*, 2 ml per well) in a 6-well polylysine-coated plate.

-44-

2. The culture medium is decanted and the plate washed with 2 ml of assay buffer (50 mM HEPES, 260 mM sucrose, 5.4 mM KCl, 1.8 mM CaCl₂, 0.8 mM MgSO₄, 5.5 mM glucose) at room temperature.
3. The assay buffer is decanted and 1 ml of assay buffer, containing 3
5 $\mu\text{Ci/ml}$ ⁸⁶Rb, with 5mM ouabain and agonist or antagonist in a concentration to effect a maximum response, is added.
4. The plate is incubated on ice at 1°C for 4 min.
5. The buffer is decanted into a waste container and each well was washed with 3 ml of assay buffer, followed by two washes of 2 ml each.
- 10 6. The cells are lysed with 2 x 0.5 ml of 0.2% SDS per well and transferred to a scintillation vial containing 5 ml of scintillation fluid.
7. The radioactivity contained in each vial 5 is measured and the data calculated. Positive control cells provided the following data in this assay:

15		PC12		IMR32	
		EC ₅₀	Maximum Response	EC ₅₀	Maximum Response
20	Agonist				
	nicotine	52 μM	2.1X ^a	18 μM	7.7X ^a
	CCh*	35 μM	3.3X ^b	230 μM	7.6X ^c
	Cytisine	57 μM	3.6X ^d	14 μM	10X ^e
	Antagonist				
25	d-tubocurarine	0.81 μM		2.5 μM

^a 200 μ M nicotine^b 300 μ M CCh^c 3mM CCh^d 1mM cytisine^e 100 μ M cytisine^f nd = not determined

5

D. Electrophysiological Analysis of Mammalian Cells Transfected with Human Neuronal nAChR Subunit-encoding DNA

10

Electrophysiological measurements may be used to assess the activity of recombinant receptors or to assess the ability of a test compound to potentiate, antagonize or otherwise modulate the magnitude and duration of the flow of cations through the ligand-gated recombinant nAChR. The function of the expressed neuronal nAChR can be assessed by a variety of electrophysiological techniques, including two-electrode voltage clamp and patch clamp methods. The cation-conducting channel intrinsic to the nAChR opens in response to acetylcholine (ACh) or other nicotinic cholinergic agonists, permitting the flow of transmembrane current carried predominantly by sodium and potassium ions under physiological conditions. This current can be monitored directly by voltage clamp techniques. In preferred embodiments, transfected mammalian cells or injected oocytes are analyzed electrophysiologically for the presence of nAChR agonist-dependent currents.

15

20

E. Fluorescent Indicator-Based Assays

25

Activation of the ligand-gated nAChR by agonists leads to an influx of cations, including Ca^{++} , through the receptor channel. Ca^{++} entry into the cell through the channel can induce release of calcium contained in intracellular stores. Monovalent cation entry into the cell through the channel can also result in an increase in cytoplasmic Ca^{++} levels through depolarization of the membrane and subsequent activation of voltage-dependent calcium channels. Therefore, methods of detecting transient

30

-46-

increases in intracellular calcium concentration can be applied to the analysis of functional nicotinic nAChR expression. One method for measuring intracellular calcium levels relies on calcium-sensitive fluorescent indicators.

- 5 Calcium-sensitive indicators, such as fluo-3 (Catalog No. F01241, Molecular Probes, Inc., Eugene, OR), are available as acetoxymethyl esters which are membrane permeable. When the acetoxymethyl ester form of the indicator enters a cell, the ester group is removed by cytosolic esterases, thereby trapping the free indicator in the cytosol.
- 10 Interaction of the free indicator with calcium results in increased fluorescence of the indicator; therefore, an increase in the intracellular Ca^{2+} concentration of cells containing the indicator can be expressed directly as an increase in fluorescence. An automated fluorescence detection system for assaying nicotinic nAChR has been described (see,
- 15 U.S. Patent Application Serial Nos. 08/229,150, 08/244,985, 08/434,511, and 08/434,968 and corresponding published International PCT Patent Application No. US92/11090; see, also, published International PCT application No. 96/05488).

- HEK cells that are transiently or stably co-transfected with DNA
- 20 encoding appropriate α and/or β subunits and α_6 and β_3 subunits are analyzed for expression of functional recombinant nAChR using the automated fluorescent indicator-based assay. The assay procedure is as follows. Untransfected HEK cells and HEK cells co-transfected with DNA encoding the appropriate α and β subunits are plated in the wells of a 96-
- 25 well microtiter dish and loaded with fluo-3 by incubation for 2 hours at 20°C in a medium containing 20 μM fluo-3, 0.2% Pluronic F-127 in HBS (125 mM NaCl, 5 mM KCl, 1.8 mM CaCl_2 , 0.62 mM MgSO_4 , 6 mM glucose, 20 mM HEPES, pH 7.4). The cells are then washed with assay buffer (i.e., HBS). The antagonist d-tubocurarine is added to some of the

-47-

wells at a final concentration of 10 μ M. The microtiter dish is then placed into a fluorescence plate reader and the basal fluorescence of each well is measured and recorded before addition of agonist, e.g., 200 μ M nicotine, to the wells. The fluorescence of the wells is monitored

5 repeatedly during a period of approximately 60 seconds following addition of nicotine.

The fluorescence of the untransfected HEK cells does not change after addition of nicotine. In contrast, the fluorescence of the co-transfected cells, in absence of d-tubocurarine, increases dramatically
10 after addition of nicotine to the wells. This nicotine-stimulated increase in fluorescence is not observed in co-transfected cells that had been exposed to the antagonist d-tubocurarine. Such results demonstrate that the co-transfected cells express functional recombinant nAChR that are activated by nicotine and blocked by d-tubocurarine.

15

While the invention has been described in detail with reference to certain preferred embodiments thereof, it will be understood that modifications and variations are within the spirit and scope of that which is described and claimed.

20

Since modifications will be apparent to those of skill in this art, it is intended that this invention be limited only by the scope of the appended claims.

Summary of Sequences

Sequence ID No. 1 is a nucleotide sequence encoding an α_2 subunit of a human neuronal nicotinic acetylcholine receptor, and the deduced amino acid sequence thereof.

5 Sequence ID No. 2 is the amino acid sequence of the α_2 subunit of a human neuronal nicotinic acetylcholine receptor set forth in Sequence ID No. 1.

Sequence ID No. 3 is a nucleotide sequence encoding a α_3 subunit of a human neuronal nicotinic acetylcholine receptor, and the deduced
10 amino acid sequence thereof.

Sequence ID No. 4 is the amino acid sequence of the α_3 subunit of a human neuronal nicotinic acetylcholine receptor set forth in Sequence ID No. 3.

Sequence ID No. 5 is a nucleotide sequence encoding an α_4 subunit
15 of a human neuronal nicotinic acetylcholine receptor, and the deduced amino acid sequence thereof.

Sequence ID No. 6 is the amino acid sequence of the α_4 subunit of a human neuronal nicotinic acetylcholine receptor set forth in Sequence ID No. 5.

20 Sequence ID No. 7 is a nucleotide sequence encoding an α_5 subunit of a human neuronal nicotinic acetylcholine receptor, and the deduced amino acid sequence thereof.

Sequence ID No. 8 is the amino acid sequence of the α_5 subunit of a human neuronal nicotinic acetylcholine receptor set forth in Sequence
25 ID No. 7.

Sequence ID No. 9 is a nucleotide sequence encoding an α_6 subunit of a human neuronal nicotinic acetylcholine receptor, and the deduced amino acid sequence thereof.

-92-

Sequence ID No. 10 is the amino acid sequence of the α_6 subunit of a human neuronal nicotinic acetylcholine receptor set forth in Sequence ID No. 9.

5 Sequence ID No. 11 is a nucleotide sequence encoding an α_7 subunit of a human neuronal nicotinic acetylcholine receptor, and the deduced amino acid sequence thereof.

Sequence ID No. 12 is the amino acid sequence of the α_7 subunit of a human neuronal nicotinic acetylcholine receptor set forth in Sequence ID No. 11.

10 Sequence ID No. 13 is a nucleotide sequence encoding a β_2 subunit of a human neuronal nicotinic acetylcholine receptor, and the deduced amino acid sequence thereof.

Sequence ID No. 14 is the amino acid sequence of the β_2 subunit of a human neuronal nicotinic acetylcholine receptor set forth in
15 Sequence ID No. 13.

Sequence ID No. 15 is a nucleotide sequence encoding a β_3 subunit of a human neuronal nicotinic acetylcholine receptor, and the deduced amino acid sequence thereof.

Sequence ID No. 16 is the amino acid sequence of the β_3 subunit
20 of a human neuronal nicotinic acetylcholine receptor set forth in Sequence ID No. 15.

Sequence ID No. 17 is a nucleotide sequence encoding a β_4 subunit of a human neuronal nicotinic acetylcholine receptor, and the deduced amino acid sequence thereof.

25 Sequence ID No. 18 is the amino acid sequence of the β_4 subunit of a human neuronal nicotinic acetylcholine receptor set forth in Sequence ID No. 17.

-93-

Sequence ID No. 19 is a nucleotide sequence encoding a variant α_6 subunit of a human neuronal nicotinic acetylcholine receptor, and the deduced amino acid sequence thereof.

Sequence ID No. 20 is the amino acid sequence of the α_6 subunit
5 of a human neuronal nicotinic acetylcholine receptor set forth in
Sequence ID No. 19.

-94-

THAT WHICH IS CLAIMED:

1. An isolated nucleic acid molecule, comprising a sequence of nucleotides encoding an α_6 subunit of a human neuronal nicotinic acetylcholine receptor.
- 5 2. The molecule of claim 1, wherein the α_6 subunit comprises the sequence of amino acids set forth in SEQ ID NO:10 or functional equivalents thereof.
3. The molecule of claim 1, wherein the α_6 subunit comprises the sequence of amino acids set forth in SEQ ID NO:10
- 10 4. The molecule of claim 1, wherein the α_6 subunit comprises the sequence of amino acids set forth in SEQ ID NO:20 or functional equivalents thereof.
5. The molecule of claim 1, wherein the α_6 subunit comprises the sequence of amino acids set forth in SEQ ID NO:20.
- 15 6. The molecule of claim 1, wherein the sequence of nucleotides hybridizes to nucleotides 143-1624 set forth in SEQ ID NO:9 under high stringency conditions, or
the sequence of nucleotides hybridizes under high stringency conditions to nucleotides 143-1579 set forth in SEQ ID NO:19.
- 20 7. The molecule of claim 1, comprising nucleotides 143-1624 set forth in SEQ ID NO:9 or functional equivalents thereof.
8. The molecule of claim 1, comprising nucleotides 143-1624 set forth in SEQ ID NO:9.
9. The molecule of claim 1, comprising nucleotides 143-1579
25 set forth in SEQ ID NO:19 or functional equivalent thereof.
10. The molecule of claim 1, comprising nucleotides 143-1579 set forth in SEQ ID NO:19.

-95-

11. An isolated nucleic acid molecule, comprising a sequence of nucleotides encoding a β_3 subunit of a human neuronal nicotinic acetylcholine receptor.

12. The molecule of claim 11, wherein the β_3 subunit comprises the sequence of amino acids set forth in SEQ ID NO:16 or functional equivalents thereof.

13. The molecule of claim 11, wherein the β_3 subunit comprises the sequence of amino acids set forth in SEQ ID NO:16.

14. The molecule of claim 11, comprising a sequence of nucleotides that hybridizes under high stringency conditions to nucleotides 98-1471 set forth in SEQ ID NO:15.

15. The molecule of claim 11, comprising nucleotides 98-1471 set forth in SEQ ID NO:15 or functional equivalents thereof.

16. The molecule of claim 11, comprising nucleotides 98-1471 set forth in SEQ ID NO:15.

17. A single-stranded nucleic acid of at least 27 bases in length, comprising any 27 contiguous bases set forth in SEQ ID NO:9 or SEQ ID NO:19 or the complement thereof.

18. A single-stranded nucleic acid of at least 28 bases in length, comprising any 28 contiguous bases set forth in the first 105 nucleotides translated sequence set forth in SEQ ID NO:15 or the complement thereof.

19. The nucleic acid of claim 17 or claim 18 that is labeled.

20. The nucleic acid of claim 19 that is labeled with ^{32}P .

21. A method for isolating DNA encoding a human nicotinic acetylcholine receptor subunit, comprising screening a library with the nucleic acid of claim 19, and isolating clones that hybridize under conditions of at least low stringency to the nucleic acid of claim 19.

-96-

22. The method of claim 21, wherein the isolated clones hybridize under conditions of high stringency.

23. The method of claim 21 or claim 22, further comprising identifying those clones that encode an α_6 or β_3 subunit.

5 24. Cells, comprising a nucleic acid molecule of claim 1, wherein the cells are prokaryotic cells or eukaryotic cells and the nucleic acid is heterologous to the cells.

25. The cells of claim 24 that are mammalian cells or amphibian oöcytes.

10 26. The cells of claim 24, further comprising heterologous nucleic acid encoding a β subunit of human neuronal nicotinic acetylcholine receptor.

27. The cells of claim 26, wherein the β subunit is selected from β_2 , β_3 or β_4 .

15 28. The cells of claim 26, wherein the β subunit is β_3 .

29. The cells of claim 24, wherein the cells express functional neuronal nicotinic acetylcholine receptors that contain one or more subunits encoded by the heterologous nucleic acid.

20 30. Cells, comprising a nucleic acid molecule of claim 11, wherein the cells are prokaryotic cells or eukaryotic cells, and the nucleic acid molecule is heterologous to the cells.

31. The cells of claim 30 that are mammalian cells or amphibian oöcytes.

25 32. The cells of claim 31, further comprising heterologous nucleic acid encoding an α subunit of a human neuronal nicotinic acetylcholine receptor.

33. The cells of claim 32, wherein the α subunit is selected from α_2 , α_3 , α_4 , α_5 , α_6 or α_7 .

-97-

34. The cells of claim 30 that express functional neuronal nicotinic acetylcholine receptors that contain one or more subunits encoded by the heterologous nucleic acid.

35. The cells of claim 31 that express functional neuronal
5 nicotinic acetylcholine receptors that contain one or more subunits encoded by the heterologous nucleic acid.

36. The molecule of claim 1 or claim 11 that is DNA.

37. The molecule of claim 1 or claim 11 that is RNA.

38. A method of screening compounds to identify compounds
10 that modulate the activity of human neuronal nicotinic acetylcholine receptors, the method comprising determining the effect of a test compound on the neuronal nicotinic acetylcholine receptor activity in cells of claim 24 or claim 30 compared to the effect on control cells or to the neuronal nicotinic acetylcholine receptor activity of the cells in the
15 absence of the compound.

39. A substantially pure human neuronal nicotinic acetylcholine receptor α_6 subunit.

40. A substantially pure recombinant human neuronal nicotinic acetylcholine receptor, comprising an α_6 human neuronal nicotinic
20 acetylcholine receptor subunit.

41. The nicotinic acetylcholine receptor of claim 40, further comprising a human neuronal nicotinic acetylcholine receptor β subunit.

42. A substantially pure human neuronal nicotinic acetylcholine receptor β_3 subunit.

25 43. A substantially pure recombinant human neuronal nicotinic acetylcholine receptor, comprising an β_3 human neuronal nicotinic acetylcholine receptor subunit.

-98-

44. The neuronal nicotinic acetylcholine receptor of claim 31, further comprising at least one human neuronal nicotinic acetylcholine receptor α subunit.

45. A method for identifying functional neuronal nicotinic acetylcholine receptor subunits and combinations thereof, comprising:

- (a) introducing a nucleic acid molecule of claim 1 into eukaryotic cells; and
- (b) detecting neuronal nicotinic acetylcholine receptor activity in the cells of step (a), wherein the activity is mediated by a receptor containing a subunit encoded by the introduced molecule.

46. The method of claim 45, further comprising, introducing nucleic acid encoding one or more β or α subunits of a human neuronal nicotinic acetylcholine receptor.

47. A method for identifying functional neuronal nicotinic acetylcholine receptor subunits and combinations thereof, comprising:

- (a) introducing a nucleic acid molecule of claim 11 into eukaryotic cells; and
- (b) detecting neuronal nicotinic acetylcholine receptor activity in the cells of step (a), wherein the activity is mediated by a receptor containing a subunit encoded by the introduced molecule.

48. The method of claim 47, further comprising, introducing nucleic acid encoding one or more β or α subunits of a human neuronal nicotinic acetylcholine receptor.

49. The nucleic acid of claim 1 or claim 11 that is mRNA.

50. Isolated cells containing the mRNA of claim 49.

51. Cells of claim 51, further comprising mRNA encoding an additional α or β subunit of a human neuronal nicotinic acetylcholine receptor.

-99-

52. An isolated nucleic acid molecule, comprising nucleotides
98-211 of SEQ ID NO:15.

INTERNATIONAL SEARCH REPORT

International Application No
PCT/US 96/09775

A. CLASSIFICATION OF SUBJECT MATTER
IPC 6 C12N15/12 C12N15/85 C12N5/10 C07K14/705 C12Q1/02

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 6 C07K C12Q

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	NEUROSCIENCE LETTERS, vol. 155, no. 2, 11 June 1993, pages 136-139, XP000611449 WILLOUGHBY, J.: "Molecular cloning of a human neuronal nicotinic acetylcholine receptor beta 3-like subunit"	11,12, 14,15, 18-23, 30,36,37
Y	see the whole document & DATABASE EMBL Heidelberg, BRD AC X67513, Q05901, 10 September 1992 WILLOUGHBY, J.: see abstract --- -/-	31-35, 38, 42-44, 47-51

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

* Special categories of cited documents :

- *A* document defining the general state of the art which is not considered to be of particular relevance
- *E* earlier document but published on or after the international filing date
- *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- *O* document referring to an oral disclosure, use, exhibition or other means
- *P* document published prior to the international filing date but later than the priority date claimed

- *T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- *X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- *Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- *&* document member of the same patent family

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US 96/09775

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
Please see Further Information sheet enclosed.
2. ☐ Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

☐ The additional search fees were accompanied by the applicant's protest.

☐ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FR M PCT/SA/210

Remark : The claim 44 in it's present form does not make any sense, the claim therefore was interpreted as : Claim 44 "the neuronal nicotinic acetylcholine receptor of Claim 43, further comprising at least one human neuronal nicotinic acetylcholine and subunit.
